# STRUCTURAL HEALTH MONITORING

Structural health monitoring (SHM) uses sensors that are permanently placed on a structure to monitor the structural behaviour over time. These sensors should be affordable, lightweight, and unobtrusive so as not to interfere with the structural strength or behaviour.

- Why monitor a structure?
- What can be measured?
- Different sensors
- Material properties
- Restrained vs free behavior
- Environmental conditions
- Installation on site
- Logging
- How much will it cost?
- What can go wrong?
- Data management
- Examples of monitoring projects

# WHY MONITOR A STRUCTURE?

Structural Health Monitoring is used to detect and quantify changes to the material and geometry of a structure over time. Careful analysis of specific measurement points can be used to:

- Detect damage
  - Facilitate performance based design
  - Assess the condition of the structure
  - Predict remaining service life
- 
- What is the cost of not monitoring a structure? (consequences of damage to structure?)
  - Could structural health monitoring lead to a CO<sub>2</sub> saving? (i.e. not having to build a new structure)

# WHAT CAN BE MEASURED?

- Temperature
- Strain
- Pressure
- Acceleration
- Displacement
- Tilt (relative displacement)

# SENSORS - TEMPERATURE

## Thermistors

- a type of resistor whose resistance is strongly dependent on temperature. The resistance difference is measured and temperature can be calculated.
- Fairly accurate  $\pm 0.2$  °C from 0°C to 70°C
- good long-term stability

## Thermocouples

- an electrical device made up of two wire of different materials that form a junction. The voltage that can be measured between the wires is temperature dependent.

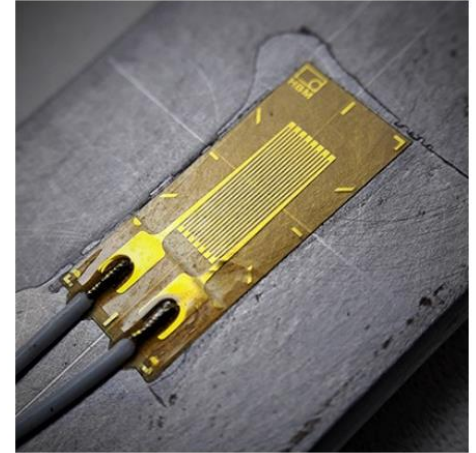

# SENSORS - STRAIN

## Electrical resistance strain gauges

- Measure the change in electrical resistance across a thin conductive foil. A gauge factor is used to convert the change in resistance to the change in length
- Short term loading – readings can drift with time
- Configuration is important
- Static / dynamic loads

## Vibrating wire strain gauges

- A tensioned wire, when plucked, vibrates at a frequency that is proportional to the strain in the wire
- Long term loading
- Static / dynamic loads
- Temperature also measured

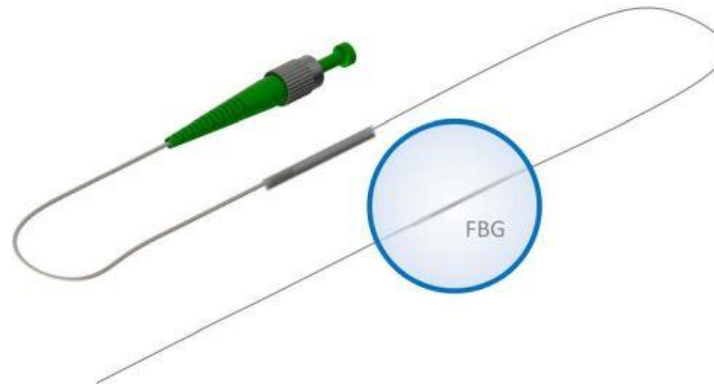

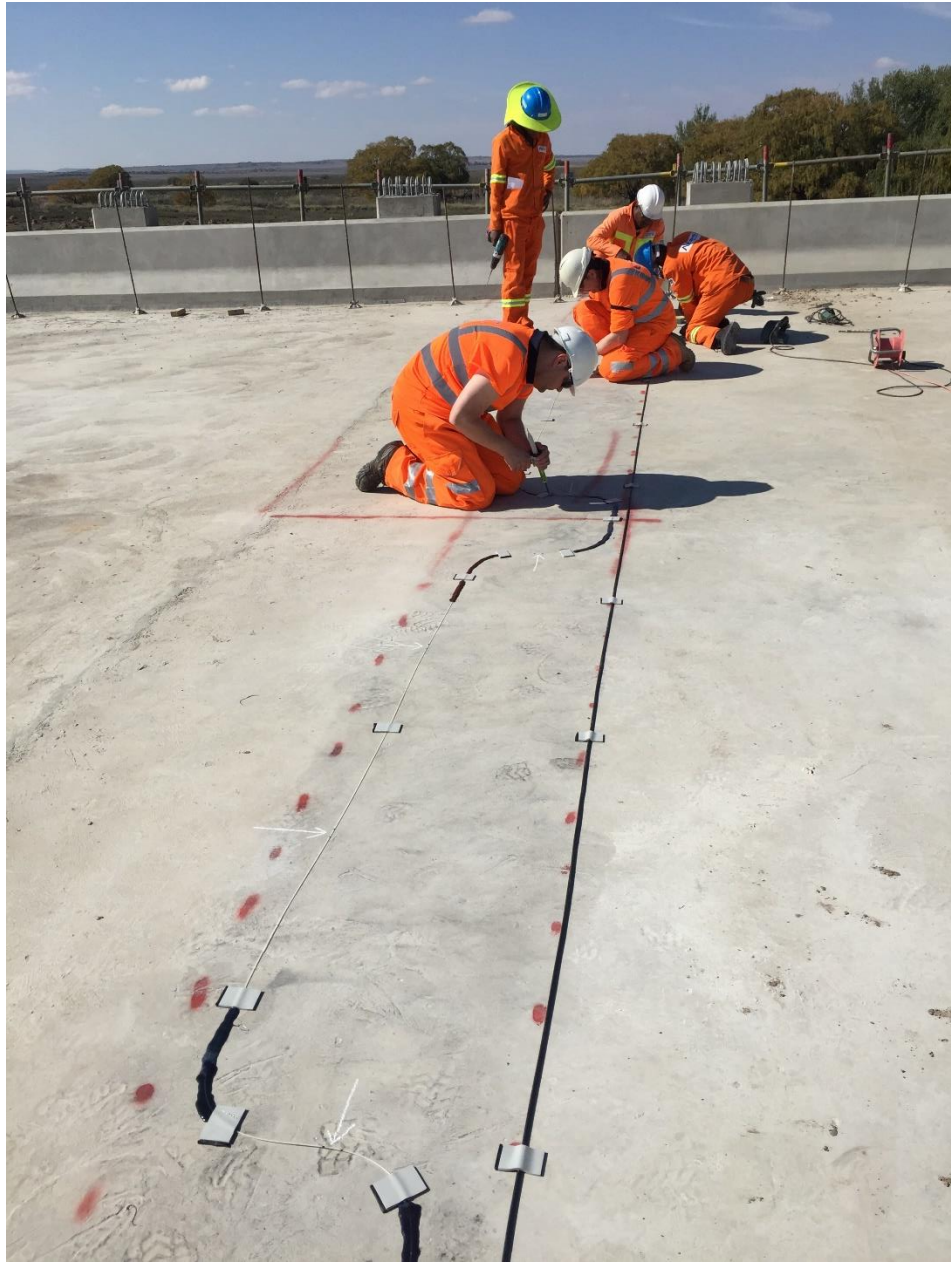

# SENSORS - STRAIN

## Fibre bragg gratings (FBG's)

- Normal fibers have uniform refractive index along their length
- In FBG's the refractive index of the core changes at specific points
- The change in light wave length measured at these specific points, and strain can be calculated from this.
- Non-destructive testing; multiple sensors on a string; light weight; can measure dynamic loading ( $> 50\text{Hz}$  for dynamic measurements)

# SENSORS – EARTH PRESSURE

## Pressure cells

- The vibrating wire pressure cells are based on vibrating wire technology.
- A type of sensor that converts stress or pressure into a measurable and readable electrical unit.
- Used to measure total stress in various geotechnical construction fields.

# SENSORS – TILT

## Tilt meter

- Sensitive inclinometer designed to measure very small changes from the vertical level, either on the ground or in structures

UNIVERSITEIT VAN PRETORIA  
UNIVERSITY OF PRETORIA  
YUNIBESITHI YA PRETORIA

Faculty of Engineering,  
Built Environment and  
Information Technology

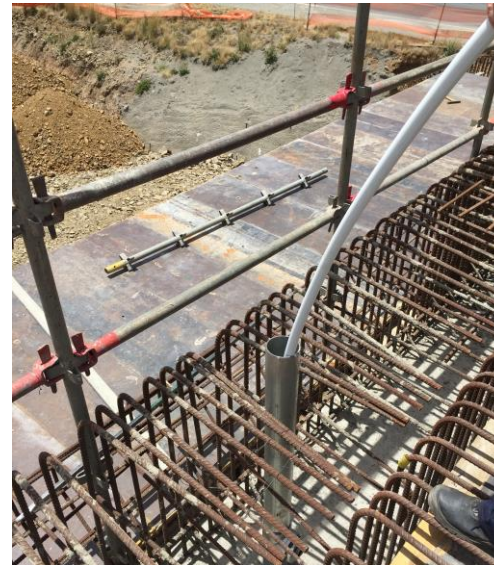

Fakulteit Ingenieurswese, Bou-omgewing en  
Inligtingtegnologie / Lefapha la Boetšenere,  
Tikologo ya Kago le Theknolotši ya Tshedimošo

# SENSORS – TILT

## Shape Accel Array

- Chain of rigid segments connected by flexible joints.
- Joints are designed to resist twist but allow the segments to tilt in x, y and z directions
- Relative displacement can be calculated

# SENSORS – ACCELERATION

## Accelerometers

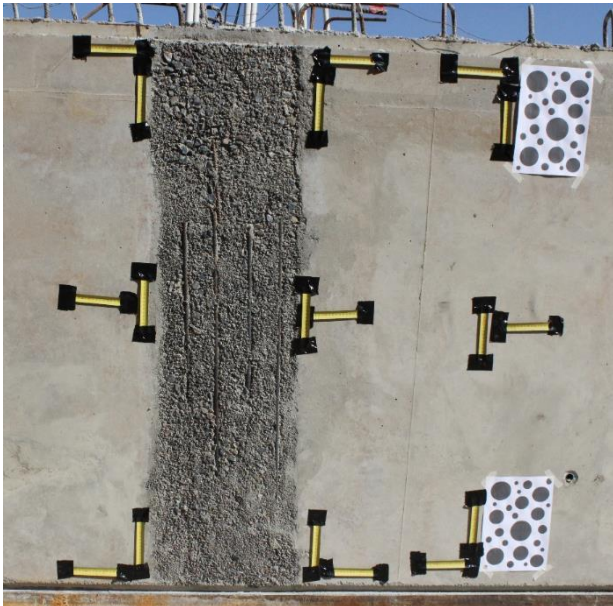

- Measures the acceleration of any body or object.
- Natural frequency - modal reactions change if there is damage
- Mobile apps can offer good accelerometers – just as good as bought ones.
- Smart phone app used (e.g. pothole detection)
- Fast Fourier transformation can be used to calculate deflection.
- In the future we might be able to use a phone to do a simple modal vibration analysis on slabs.

# SENSORS – VISUAL TECHNIQUES

## Particle image velocimetry (PIV)

- Measurement displacement taking a series of photos during loading and then using software to post-process the photo image data.

PIV measurements done on a prestressed beam while pre-stressing cables were cut

Tikologo ya Kago le Theknolotši ya Tshedimošo

# HOW MUCH WILL IT COST?

- Sensors
- Installation – site location
- Cabling
- Power supply
- Logging
- Data analysis

# WHAT CAN GO WRONG

- Leaving sensors or ducting out of concrete cast  
*Design and detailing of SHM system – drawings, fixing details etc*
- Strange readings!  
*Build in redundancy to the SHM system*
- Program delays  
*This affects the price*
- Sensors in the incorrect position / orientation or covered incorrectly  
*Don't just leave it to the Contractor to sort out*
- Damage to cables  
*Log during concrete placement*
- Theft / vandalism  
*Place storage boxes, solar panels etc. out of the general view*

# DATA MANAGEMENT

- Big data
- Data analysis and management
- Warning systems
- How does restraint effect the readings?

# EXAMPLES OF MONITORING PROJECTS

- Van Zylspruit bridge (fully integral bridge)
- Javett Centre bridge
- Multiple Ply Timber trusses
- Wind turbine foundations

# CONCLUSION

*“When you can measure what you are speaking about, and express it in numbers, you know something about it...” Lord Kelvin 1891*

- We are modelling structures with very sophisticated software more “accurately” but what is really happening in the structure?
- Extrapolated designs – taller, longer spans, more slender, but when should we stop?
- If we don’t measure, we don’t know!
