# Background

- 580m span cable stay bridge
- Initial focus was thermal effects on large foundations during curing.
  - 4 gravity Anchors 50x10x17 each
  - 4 Pylon bases 12x12x8 each
- The ladder deck, at 3m x 2m cross section was comparatively insignificant...

# Ladder deck – The Challenge

- 24m long deck with two edge beams
- Large axial compression & bending due to cables
- Very congested – 3 layers Y40@150
- Restricted – end is encased in steel box with dense rebar to transfer steel deck box axial load to deck
- Previous history with mix design constituents where in under certain conditions fresh concrete appears to undergo a type of flash set

# Ladder deck – Thermal

- Specification:
  - 65 MPa
  - 85/15 OPC/GGBS:  strength,  thermal
  - Maximum T 70°C during curing
  - Maximum  $\Delta T$  22°C between inside and outside

## Rebar Congestion

Add rebar photos in box

## Rebar congestion in ladder deck into steel box girders

# Ladder deck - Solutions

- 7 different mix designs trialed, focusing on:
  - Workability (SCC type properties)
  - Strength
  - Mitigating thermal effects

# Ladder deck - Solutions

- Changed 19mm coarse aggregate to a 14mm due to congestion.
- Concerns during trials of early set properties
- Designed for slump of 210mm, but early mix designs set after 15 minutes
- Final 65MPa required 535kg/m<sup>3</sup> binder and changed testing to 56d to address slower strength gain

## Ladder deck – Thermal Solutions

- To reduce thermal effects the following were evaluated:
  - Reduced input temperature (aggregate and water)
  - Plumbing to cool curing concrete
  - Insulation
  - Splitting pour
  - Modifying mix design to reduce temperatures
- Increasing GGBS lowered temperatures, but slowed rate of strength gain.

# Ladder deck – Thermal Solutions

- Wits temperature model developed by Professor Ballim (2004).
- Finite Difference Method to solve for heat flow.
- Predicts time-temperature profile for 2D elements.

# Finite difference model approach

Solve 2-D Fourier Equation:

$$\rho \cdot C_p \cdot \frac{\partial T}{\partial t} = k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) + \frac{\partial q}{\partial t}$$

Boundary Conditions:

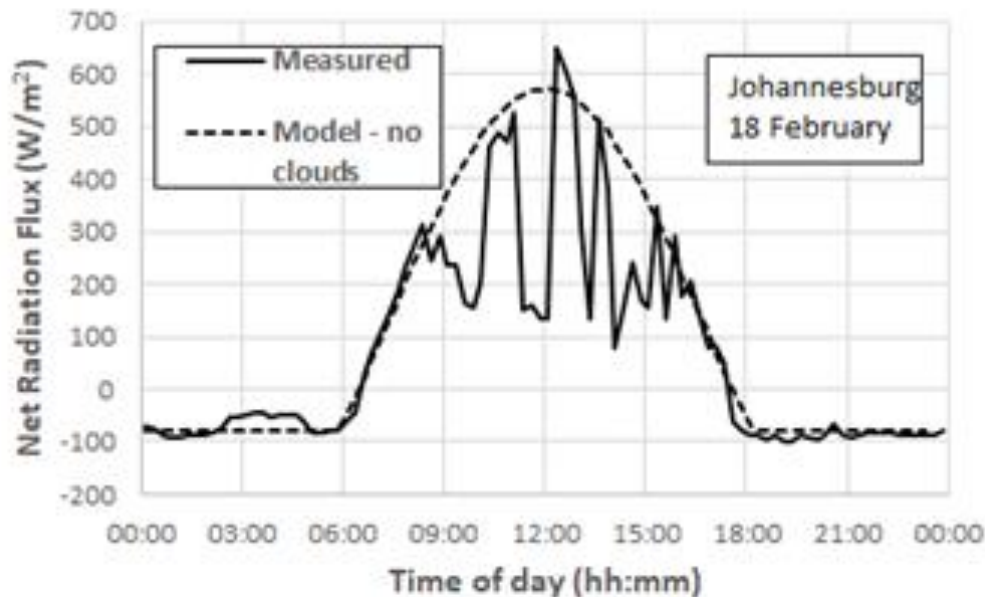

- 1<sup>st</sup> layer cast on rock
- Side surfaces with steel or timber formwork
- Varying diurnal ambient temperature
- Top surface exposed to air and solar radiation
- Long-wave exit radiation at night

Note use of maturity heat rate  $\frac{\partial q}{\partial M}$

System taken as symmetrical about vertical axis – analyse left half of concrete layers

# Net solar radiation as a boundary condition

Radiation on a horizontal surface Johannesburg, February

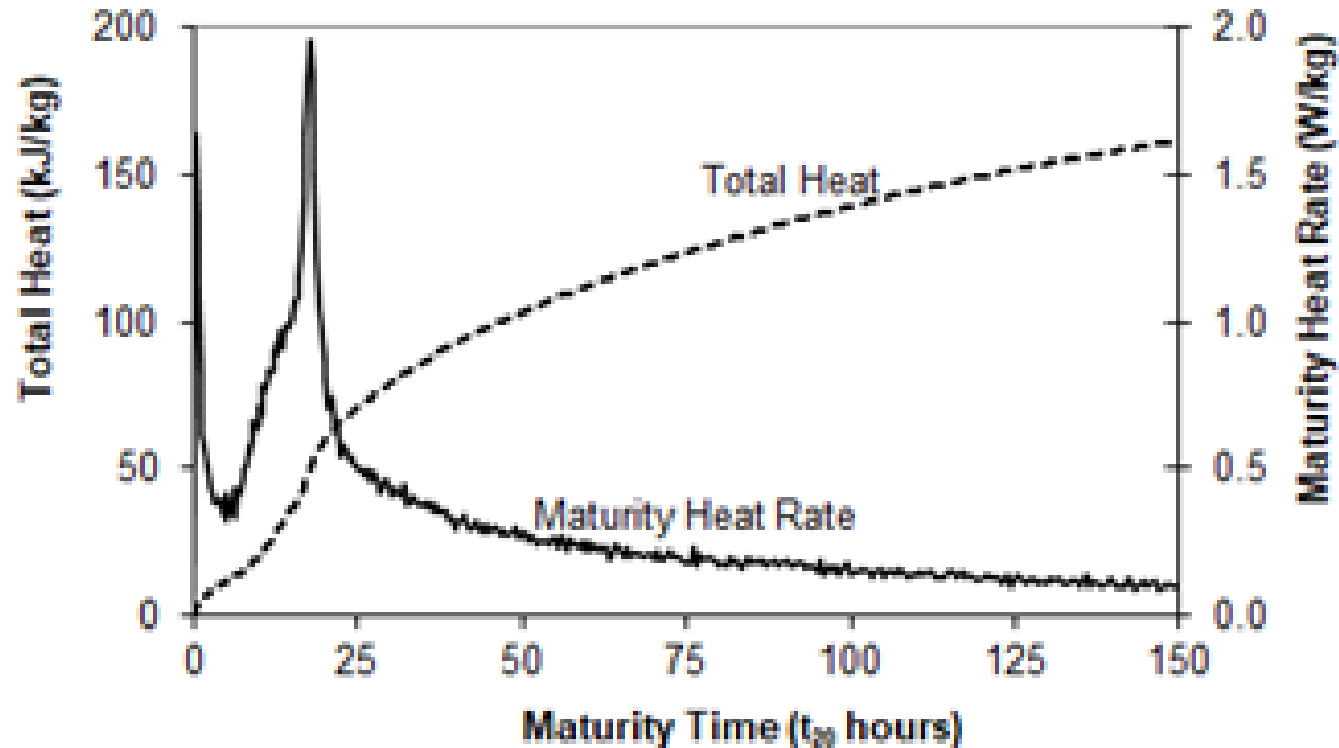

$$\text{For } t_{d,am} < t_d < t_{d,pm}: \\ R_n = A + B \cos(C \cdot t_d + D)$$

$$\text{For } t_d < t_{d,am} \text{ and } t_d > t_{d,pm}: \\ R_n = -80 \text{ W/m}^2$$

Note: Sinusoidal variation in ambient temperature between likely maximum and minimum Daytime temperatures

# Maturity heat rate for Fourier Equation

(measured in WITS University adiabatic calorimeter for the proposed concrete materials and mixture design)

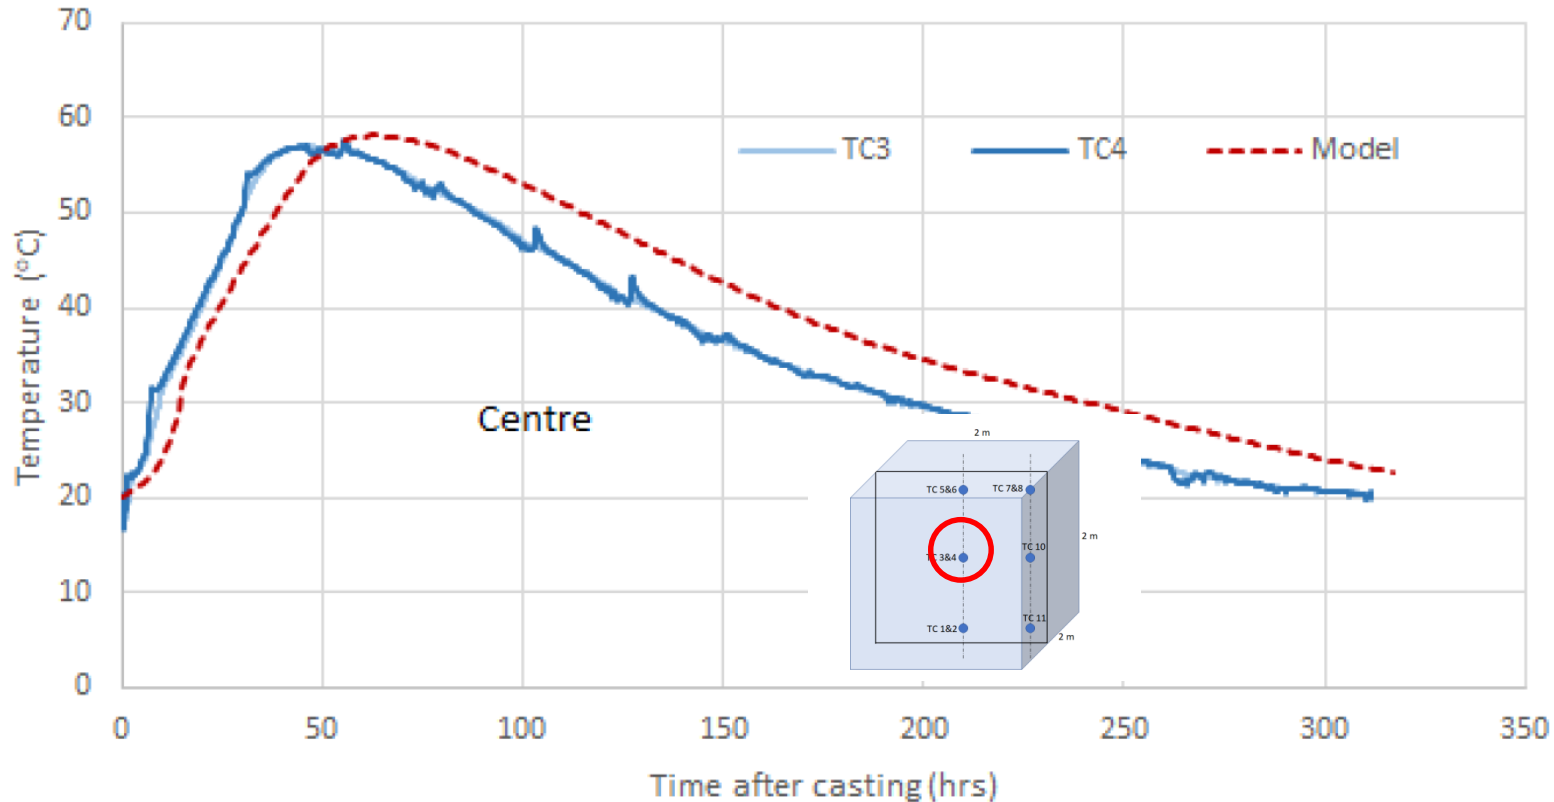

# Ladder deck – Thermal Solutions
